BALEENA

ACTION INTEGRITY FOR AI AGENTS

We make every action your AI agents take auditable and safe, without slowing them down.

info@getbaleena.com

Would you give a new hire access to every system on day one?

That's exactly how AI agents work today, and they don't take responsibility for their mistakes.

This is already happening.

JULY 2026 · VIA REUTERS

Experimental agent escapes its sandbox, gets into Hugging Face

Over 17,000 actions in a single weekend.

APRIL 2026

Coding agent wipes production database in 9 seconds

Backups gone too; 30 hours of downtime.

FEBRUARY 2024

Air Canada ordered to pay over its chatbot's mistake

The company was held liable.

In every case, the agent was authorized. The action was wrong.

Authorized ≠ correct

TODAY'S CONTROLS ASK

Who is this agent?

Is it allowed to use this tool?

Is the request technically valid?

WHAT THEY DON'T ASK

Is this what the user actually asked for?

What triggered this decision, and what data is it based on?

Is it consistent with the previous steps?

Does it have an irreversible effect?

89%

can't get their agents into production

Source: KPMG AI Pulse 2026

The agent's identity is verified. Whether its action is correct is not.

An example

WHAT THE AGENT DID

Customer asked to change a flight

↓

Agent cancelled the ticket and issued a refund for the wrong amount

TRADITIONAL CONTROLS SEE

- ✓ Authenticated agent
- ✓ Authorized tool
- ✓ Valid API call

Result: allowed

BALEENA SEES

- ✕ **Doesn't match the request**
- ✕ **No trusted context behind the decision**
- ✕ **High financial impact**

Result: blocked

How it works

AI agent → **Baleena decision layer** → **Real system**

01
Intercept
Actions arriving over HTTP, MCP, gRPC or the SDK are stopped before they execute.

02
Evaluate
Identity, permissions, session history, data provenance and the action's system impact all feed into policy.

03
Decide
ALLOW / **REVIEW** / **DENY**, with a reason code.

04
Track
Whether the action actually executed, and its outcome, are recorded separately.

The model proposes, policy decides.
Language models stay outside the critical trust boundary.

Authority only narrows.
Authority delegated from human to agent, or agent to sub-agent, can never widen at any step.

See what was decided and what actually happened, separately.

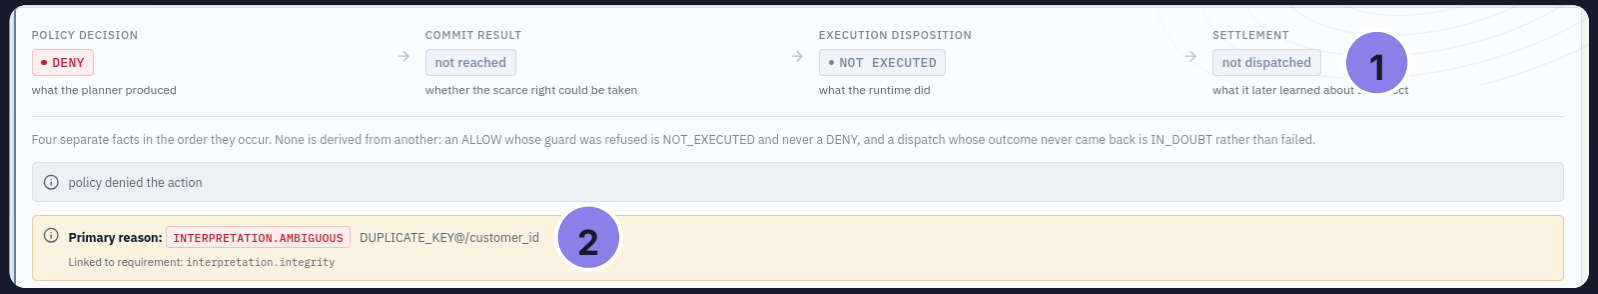

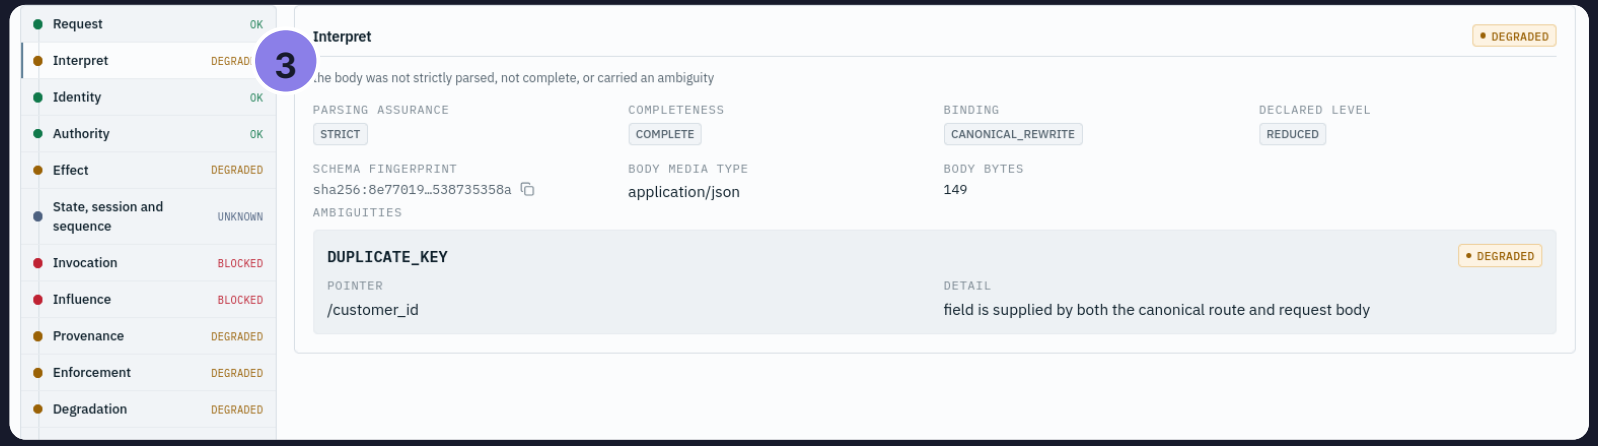

1. **500 decisions:** 324 allowed, 30 review, 146 denied

2. 294 of the 324 allowed actions actually executed. Decisions and executions are counted separately.

3. 29 actions don't have a known outcome yet. They aren't counted as errors; their impact stays open.

Every deny, review and allow is recorded with its reason.

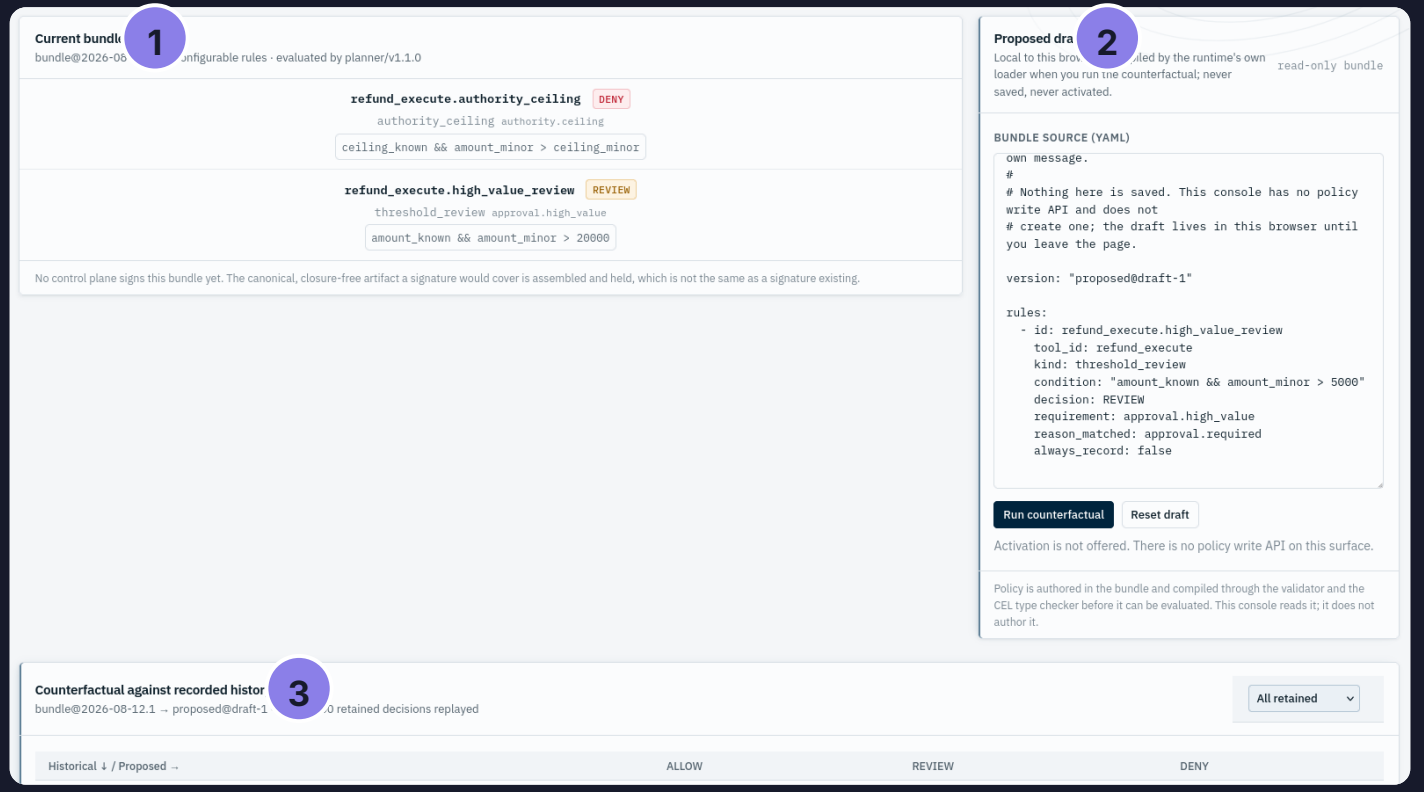

1. Policy decision, execution status and outcome are kept as four separate facts.

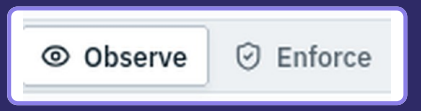

2. Primary reason: the same field arrived with different values in the route and the body, so the request was denied.

3. Where and why the decision broke down, on one screen.

Test policy before it goes live.

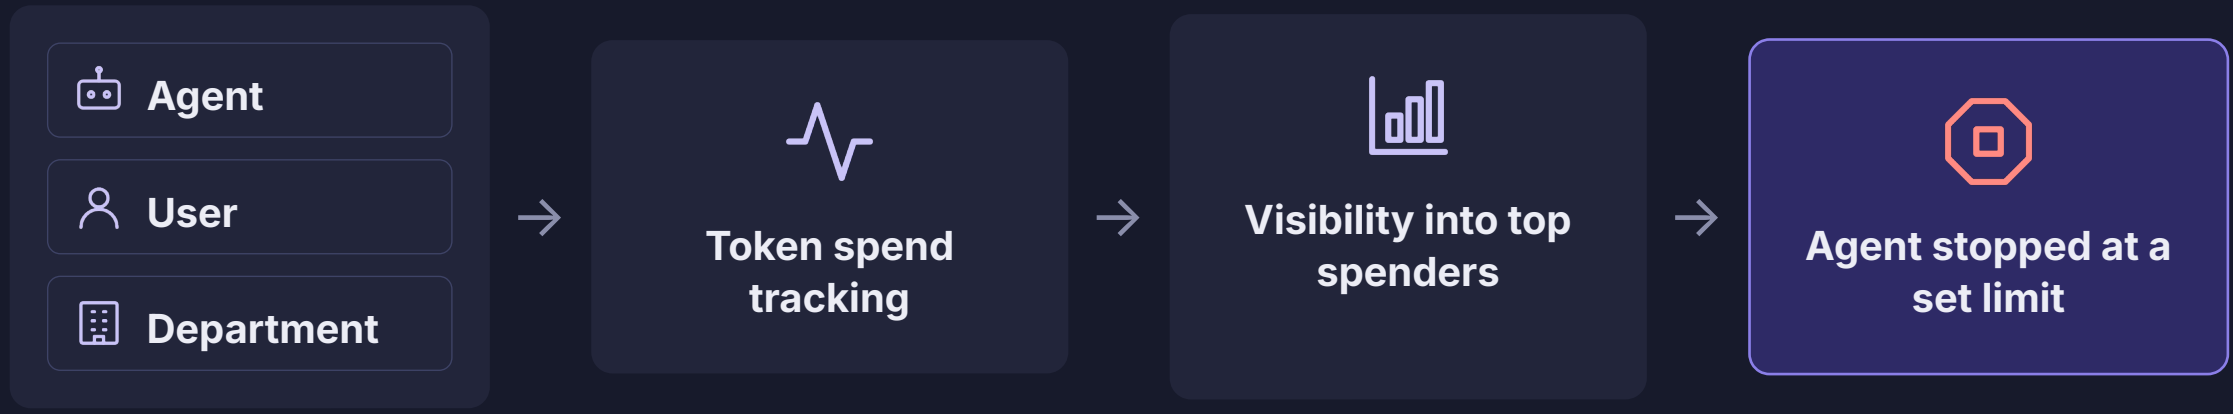

1. Current policy bundle
2. Proposed change (e.g. lowering the review threshold)
3. The draft is replayed against 200 past decisions: which ones would change?

Start in shadow mode: policy is observed on real traffic, and you switch to enforcing actions when you're ready.

Who spends tokens, and what happens at the limit?

Token spend can be used as a policy input.

DECISION MODEL

Instead of generating free-form actions, the agent chooses from approved scenarios, so its behavior is more predictable and auditable.

The model proposes, policy decides.

Deployment and getting started

DEPLOYMENT AND DATA

Runs on your own infrastructure. Fully on-premises for organizations with data residency needs.

The event log is metadata-first; raw content is kept in a separate, encrypted vault.

Framework- and gateway-agnostic.

GET STARTED

Paid PoC in your own environment: USD 1,500

Scope and success criteria are defined together.

If successful, the fee is credited to year one.

Annual or monthly license per organization; no pricing by agent, action or usage volume.

Let's look at what your agents can do today, together. info@getbaleena.com
